# Intro & set up

$M_{a,b}(\mathbf{k})$ : matrices of size  $a \times b$  over a field  $\mathbf{k}$

A vector subspace  $V \subseteq M_{a,b}(\mathbf{k})$  (of dimension  $n + 1$ ) is a **space of matrices of constant rank** if all its nonzero elements have fixed rank  $r$ .

Main questions:

1. Determine  $\ell(a, b, r)$ : max dim  $V$ , and give relations among the possible values of the parameters  $a, b, r, n$ .
2. Classification for fixed values of  $a, b, r, n$ .
3. **Construction of examples.**

## Spaces of matrices $\rightsquigarrow$ vector bundles

We look at the  $n + 1$ -dim'l space  $V$  as an  $a \times b$  matrix whose entries are linear forms (a *linear matrix*), and interpret the cokernel as a vector space varying smoothly over  $\mathbb{P}^n$ , i.e. a vector bundle!

We get an exact sequence:

$$0 \rightarrow K \rightarrow \mathcal{O}_{\mathbb{P}^n}(-m-1)^b \xrightarrow{V} \mathcal{O}_{\mathbb{P}^n}(-m)^a \rightarrow E \rightarrow 0$$

with  $K$ ,  $\mathcal{E}$ , and  $E$  v.b. on  $\mathbb{P}^n$  of rank  $b - r$ ,  $r$ , and  $a - r$  resp.

Remark. The idea of using v.b. to study and construct linear matrices of constant rank dates back to [Sylvester '86].

## Some results

- [Westwick '87]  $b - r + 1 \leq \ell(a, b, r) \leq a + b - 2r + 1$   
for  $2 \leq r \leq a \leq b$  (**not sharp**)
- [Ellia-Menegatti '15] effective value of  $\ell(a, r)$  for  $a \leq 10$
- [Illic-Landsberg '99]  $\ell_{sym}(r + 2, r) = 3$
- [Manivel-Mezzetti '05] classification of spaces of skew-symm matrices of size 6 and constant rank 4,  $\ell_{skew}(6, 4) = 3$
- [Fania-Mezzetti '11] classification of spaces of skew-symm matrices of size 8 and constant rank 6,  $\ell_{skew}(8, 6) = 3$
- [B.-Mezzetti '15] classification of  $m$ -effective pairs  $(c_1, c_2)$   
+ **explicit** construction for all pairs  
( $m$ -effective: there exists a 3-dim'l space of skew-symm matrices of size  $2c_1 + 2$ , constant rank  $2c_1$ , whose cokernel  $E$  has  $c_i(E) = c_i$ )

# Looking for explicit examples

Possible approaches:

- ★ “ad hoc” construction, e.g. [Westwick '90], or
- ★ **projection** from bigger size matrices.

Why projecting? The smaller  $n - r$  is, the easier it becomes to find indecomposable rank  $r$  bundles on  $\mathbb{P}^n$ ,

so a good strategy consists in first building a bigger matrix, and then projecting it to a smaller one of the same constant rank.

Cutting down columns (rows)  $\leftrightarrow$  taking a quotient of  $K$  (resp.  $E$ )

Example. All  $m$ -effective bundles appearing in [B.-Mezzetti '15] are quotients of bundles of the form:

$$\left(\bigoplus_{i \geq 1} \mathcal{O}_{\mathbb{P}^2}(i)^{a_i}\right) \oplus Q^b \quad \text{with } i \geq 1, a_i, b \geq 0 \text{ for all } i.$$

## Small corank

The projection technique was also used in [Fania-Mezzetti '11], but it does not work for “small corank”:

**Proposition.** Let  $V$  be a linear space of  $a \times b$  matrices of constant rank  $r$ , and  $\dim = n + 1$ .  $V$  induces by projection a space  $V'$  of  $\alpha \times \beta$  matrices of the same constant rank  $r$  and dimension  $n + 1$  for any  $\alpha \geq r + n$  and  $\beta \geq r + n$ .

**Corollary.**  $n + 1$ -dim'l spaces of matrices of constant rank **cannot be constructed via projection** as soon as  $n > \min\{\alpha - r, \beta - r\}$ .

We say that an  $n + 1$ -dim'l space of  $a \times b$  matrices of constant rank  $r$  has *small corank* if  $n > \min\{a - r, b - r\}$ .

## Vector bundles $\rightsquigarrow$ spaces of matrices?

[B.-Faenzi-Mezzetti '13]: method to prove existence of families of 4-dim'l spaces of skew-symmetric matrices of constant corank 2 (so small corank!)

Restart from the exact sequence:

$$0 \rightarrow K \rightarrow \mathcal{O}_{\mathbb{P}^n}(-m-1)^b \rightarrow \mathcal{O}_{\mathbb{P}^n}(-m)^a \rightarrow E \rightarrow 0$$

## Vector bundles $\rightsquigarrow$ spaces of matrices?

[B.-Faenzi-Mezzetti '13]: method to prove existence of families of 4-dim'l spaces of skew-symmetric matrices of constant corank 2 (so small corank!)

Restart from the exact sequence in the skew-symm. case:

$$0 \rightarrow E^*(-2m-1) \rightarrow \mathcal{O}_{\mathbb{P}^3}(-m-1)^{r+2} \rightarrow \mathcal{O}_{\mathbb{P}^3}(-m)^{r+2} \rightarrow E \rightarrow 0$$

We get a distinguished element

$$\eta \in \text{Ext}^2(E, E^*(-2m-1)) \simeq \text{Hom}_{D^b(\mathbb{P}^3)}(E, E^*(-2m-1)[2]).$$

For all  $t \in \mathbb{Z}$ , the cup product with  $\eta$  induces maps:

$$\mu_t : H^0(E(t)) \rightarrow H^2(E^*(-2m-1+t)).$$

Our distinguished elt. gives non-degeneracy conditions on the  $\mu_t$ 's.

# Vector bundles $\rightsquigarrow$ spaces of matrices?

**Idea:** take  $\text{Cone}(\eta)$ , the cone of the morphism  $\eta$ , and decompose it with respect to the standard exceptional collection  $\langle \mathcal{O}_{\mathbb{P}^3}(-m-2), \mathcal{O}_{\mathbb{P}^3}(-m-1), \mathcal{O}_{\mathbb{P}^3}(-m), \mathcal{O}_{\mathbb{P}^3}(-m+1) \rangle$ .

## Theorem I. (B.-Faenzi-Mezzetti)

$E$ : rank 2 vector bundle on  $\mathbb{P}^3$  “with the right invariants”.

The **existence of a distinguished elt.**  $\eta \in \text{Ext}^2(E, E^*(-2m-1))$  inducing the non-degeneracy conditions on the maps  $\mu_t$ 's

**is equivalent to**

the **existence of a linear matrix**  $V$ , having size  $r+2$ , constant rank  $r$ , and a twist of  $E$  as its cokernel.

Such matrix appears as differential in the decomposition of  $\text{Cone}(\eta)$ , and moreover it is **necessarily skew-symmetrizable**.

# Instanton bundles & spaces of matrices

The non-degeneracy conditions in **Theorem I** are hard to check!

It can be done in the following cases:

## Theorem II. (B.-Faenzi-Mezzetti)

- Any **2-instanton** on  $\mathbb{P}^3$  induces a skew-symmetric matrix of linear forms in 4 variables having size 10 and constant rank 8.
- General **4-instantons** on  $\mathbb{P}^3$  induce a skew-symmetric matrix of linear forms in 4 variables having size 14 and constant rank 12.

Problem: these results are **non-constructive!**

## Looking for a constructive algorithm

Remember: we want a construction vector bundle  $\rightsquigarrow$  linear matrix.

So let  $E$ : v.b. on  $\mathbb{P}^n = Proj(R)$ ,  $R = \mathbf{k}[x_0, \dots, x_n]$ .

**First idea:** look at its minimal free resolution. Even better, resolve its module of sections:  $\mathbf{E} = H_*^0(E) = \bigoplus_{t \in \mathbb{Z}} H^0(E(t))$ .

It is a graded  $R$ -module with graded Betti numbers  $\beta_{i,j}$  and minimal free resolution:

$$\cdots \longrightarrow \bigoplus_{j_1} R(-j_1)^{\beta_{1,j_1}} \longrightarrow \bigoplus_{j_0} R(-j_0)^{\beta_{0,j_0}} \longrightarrow \mathbf{E}$$

This is of course **too naïve**. The resolution is not *linear* in general!

## Linear presentation, $m$ -linearity

A graded  $R$ -module  $\mathbf{E}$  has  *$m$ -linear resolution* over  $R$  if its minimal graded free resolution, for suitable integers  $\beta_{i,m+i}$ , is of type:

$$\cdots \longrightarrow R(-m-2)^{\beta_{2,m+2}} \longrightarrow R(-m-1)^{\beta_{1,m+1}} \longrightarrow R(-m)^{\beta_{0,m}} \longrightarrow \mathbf{E}$$

That is,  $\mathbf{E}$  has a  $m$ -linear resolution if:

1.  $\mathbf{E}_r = 0$  for  $r < m$ ,
2.  $\mathbf{E}$  is generated by  $\mathbf{E}_m$ , and
3.  $\mathbf{E}$  has a resolution where all the maps are represented by matrices of **linear forms**.

$\mathbf{E}$  is  *$m$ -linearly presented up to order  $k$* , or just *linearly presented* when  $k = 1$ , if only the first  $k$  maps are matrices of linear forms.

## Truncated modules and regularity

We can get around the non-linearity of the resolution of  $\mathbf{E}$  by **truncating the graded module “in the right spot”**, namely its **regularity**  $\text{reg}(\mathbf{E})$ .  
(Can be computed as  $\max\{j - i \mid \beta_{i,j} \neq 0\}$ .)

Indeed, if  $\mathbf{E} = \bigoplus_{t \in \mathbb{Z}} \mathbf{E}_t$ , then  $\mathbf{E}_{\geq m} = \bigoplus_{t \geq m} \mathbf{E}_t$  and  $\mathbf{E}_{\geq \text{reg}(\mathbf{E})}$  always has  $m$ -linear resolution.

So we got linearity, but we still need something a bit more sophisticated! To begin with, we **lost control over the size** of the matrix (in general it will be too big!)

**(Vague) idea:** “cut off a piece” of the linear matrix from the linear resolution of  $\mathbf{E}_{\geq \text{reg}(\mathbf{E})}$ , **without modifying the rank**.

# Cutting off pieces of a linear resolution

Construction from [B.-Faenzi-Lella '16]: let  $\mathbf{E}$  and  $\mathbf{G}$  be f.g. graded  $R$ -modules with minimal graded free resolutions:

$$\dots \longrightarrow E^1 \xrightarrow{e_1} E^0 \xrightarrow{e_0} \mathbf{E}$$

$$\dots \longrightarrow G^1 \xrightarrow{g_1} G^0 \xrightarrow{g_0} \mathbf{G}$$

# Cutting off pieces of a linear resolution

Construction from [B.-Faenzi-Lella '16]: let  $\mathbf{E}$  and  $\mathbf{G}$  be f.g. graded  $R$ -modules with minimal graded free resolutions:

$\mu : \mathbf{E} \rightarrow \mathbf{G}$  morphism induces maps  $\mu^i : E^i \rightarrow G^i$ , det. up to chain homotopy.

( $\mathbf{E}$  and  $\mathbf{G}$  lin presented up to order  $j \Rightarrow$  the  $\mu^i$ 's are uniquely det. for  $i \leq j - 1$ .)

$$\begin{array}{ccccccc} \dots & \longrightarrow & E^1 & \xrightarrow{e_1} & E^0 & \xrightarrow{e_0} & \mathbf{E} \\ & & \downarrow \mu^1 & & \downarrow \mu^0 & & \downarrow \mu \\ \dots & \longrightarrow & G^1 & \xrightarrow{g_1} & G^0 & \xrightarrow{g_0} & \mathbf{G} \end{array}$$

# Cutting off pieces of a linear resolution

Construction from [B.-Faenzi-Lella '16]: let  $\mathbf{E}$  and  $\mathbf{G}$  be f.g. graded  $R$ -modules with minimal graded free resolutions:

$\mu : \mathbf{E} \rightarrow \mathbf{G}$  morphism induces maps  $\mu^i : E^i \rightarrow G^i$ , det. up to chain homotopy.

( $\mathbf{E}$  and  $\mathbf{G}$  lin presented up to order  $j \Rightarrow$  the  $\mu^i$ 's are uniquely det. for  $i \leq j - 1$ .)

$$\begin{array}{ccccccc} \cdots & \longrightarrow & ? & \longrightarrow & ? & \longrightarrow & \mathbf{F} \\ & & & & & & \downarrow \\ \cdots & \longrightarrow & E^1 & \xrightarrow{e_1} & E^0 & \xrightarrow{e_0} & \mathbf{E} \\ & & \downarrow \mu^1 & & \downarrow \mu^0 & & \downarrow \mu \\ \cdots & \longrightarrow & G^1 & \xrightarrow{g_1} & G^0 & \xrightarrow{g_0} & \mathbf{G} \end{array}$$

What can we say about the resolution of the kernel  $\mathbf{F}$ ?

# Cutting off pieces of a linear resolution

## Theorem A. (B.-Faenzi-Lella)

$\mathbf{E}$  and  $\mathbf{G}$ :  $m$ -lin presented  $R$ -modules, resp. up to order 1 and 2

$\mu : \mathbf{E} \twoheadrightarrow \mathbf{G}$  a surjective morphism, and  $\mu^i$ 's the induced maps

Then  $\mathbf{F} = \ker(\mu)$  is generated in deg  $m$  and  $m + 1$ , and moreover:

1. if  $\mu^1$  is surjective,  $\mathbf{F}$  is generated in deg  $m$  and has linear and quadratic syzygies, and  $\beta_{0,m}(\mathbf{F}) = \beta_{0,m}(\mathbf{E}) - \beta_{0,m}(\mathbf{G})$ ;
2. if moreover  $\mu^2$  is surjective,  $\mathbf{F}$  is linearly presented and  $\beta_{1,m+1}(\mathbf{F}) = \beta_{1,m+1}(\mathbf{E}) - \beta_{1,m+1}(\mathbf{G})$ .

# Cutting off pieces of a linear resolution

## Theorem A. (B.-Faenzi-Lella)

$\mathbf{E}$  and  $\mathbf{G}$ :  $m$ -lin presented  $R$ -modules, resp. up to order 1 and 2

$\mu : \mathbf{E} \twoheadrightarrow \mathbf{G}$  a surjective morphism, and  $\mu^i$ 's the induced maps

Then  $\mathbf{F} = \ker(\mu)$  is generated in deg  $m$  and  $m + 1$ , and moreover:

1. if  $\mu^1$  is surjective,  $\mathbf{F}$  is generated in deg  $m$  and has linear and quadratic syzygies, and  $\beta_{0,m}(\mathbf{F}) = \beta_{0,m}(\mathbf{E}) - \beta_{0,m}(\mathbf{G})$ ;

2.

$$\begin{array}{ccccccc} \dots & \longrightarrow & R(-m-1)^{\alpha_1-\gamma_1} & \longrightarrow & R(-m)^{\alpha_0-\gamma_0} & \longrightarrow & \mathbf{F} \\ & & \downarrow & & \downarrow & & \downarrow \\ \dots & \longrightarrow & R(-m-2)^{\alpha_2} & \longrightarrow & R(-m-1)^{\alpha_1} & \longrightarrow & R(-m)^{\alpha_0} & \longrightarrow & \mathbf{E} \\ & & \downarrow \mu^2 & & \downarrow \mu^1 & & \downarrow \mu^0 & & \downarrow \mu \\ \dots & \longrightarrow & R(-m-2)^{\gamma_2} & \longrightarrow & R(-m-1)^{\gamma_1} & \longrightarrow & R(-m)^{\gamma_0} & \longrightarrow & \mathbf{G} \end{array}$$

# Looking for constant rank matrices

Our goal is to construct **constant rank** matrices from v.b.  
What happens if the sheaves  $E = \tilde{\mathbf{E}}$  and  $G = \tilde{\mathbf{G}}$  are v.b.?

## Theorem B. (B.-Faenzi-Lella)

In the assumptions of **Theorem A** part 1, suppose also that:

- (i)  $E = \tilde{\mathbf{E}}$  and  $G = \tilde{\mathbf{G}}$  are v.b. on  $\mathbb{P}^n$  of rank  $r$  and  $s$  respectively;
- (ii) some extra “technical condition” holds.

Set  $a = \beta_{0,m}(\mathbf{E}) - \beta_{0,m}(\mathbf{G})$  and  $b = \beta_{1,m+1}(\mathbf{E}) - \beta_{1,m+1}(\mathbf{G})$ .

Then the presentation matrix  $V$  of  $\mathbf{F} = \ker(\mu)$  has a linear part of size  $a \times b$  and constant corank  $r - s$ .

Moreover  $F = \tilde{\mathbf{F}}$  is isomorphic to the kernel of  $\tilde{\mu} : E \rightarrow G$ .

Remark.  $\mu^2$  surjective  $\Rightarrow$  technical condition  
 $\nLeftarrow$

## (A lot of) explicit examples!

In the applications we consider the case when  $G = 0$ , i.e.  $\mathbf{G}$  Artinian module, so in particular  $F = \tilde{\mathbf{F}} \simeq \tilde{\mathbf{E}} = E$ .

What do we get?

A veritable **factory of examples** of constant rank matrices!

Why is it **good**?

- ★ can implement the method on a computer (Macaulay2 packages available online)
- ★ explicit examples in several cases

Why is it **better** than previously existing methods?

- ★ can avoid cumbersome computations
- ★ the method goes beyond projection method and works for small corank!

# It all comes together

Let's go back to:

$$0 \rightarrow K(t) \rightarrow \mathcal{O}_{\mathbb{P}^n}(-m-1+t)^b \rightarrow \mathcal{O}_{\mathbb{P}^n}(-m+t)^a \rightarrow E(t) \rightarrow 0.$$

We saw that an exact sequence of this type corresponds to an element  $\eta \in \text{Ext}^2(E, K)$ , which via cup product induces maps

$$\mu_t : H^0(E(t)) \rightarrow H^2(K(t)).$$

$\rightsquigarrow$  cup product with  $\eta$  gives:  $\mu = \bigoplus_t \mu_t : H_*^0(E) \rightarrow H_*^2(K)$ .

This is a morphism, homogeneous of degree 0.

For  $n \geq 3$  both cohomology groups  $H^1(\mathcal{O}_{\mathbb{P}^n}(-m+t))$  and  $H^2(\mathcal{O}_{\mathbb{P}^n}(-m-1+t))$  vanish for all  $t$ , so  $\mu$  is surjective.

So we are in a good position to apply **Theorem B!**

## It all comes together

Set  $\mathbf{E} = H_*^0(E)$  and  $\mathbf{M} = H_*^2(K)$ ,

and define  $\Phi$  as the linear map induced by the  $\mu_t$ 's:

$$\Phi : \text{Ext}^2(E, K) \longrightarrow \text{Hom}_R(\mathbf{E}, \mathbf{M})_0$$

### Theorem I, revisited.

Let  $n \geq 3$  and  $V : R(-m-1)^b \rightarrow R(-m)^a$  skew-symmetrizable of constant rank. Set  $K = \ker V$  and  $E = \text{Coker } V$ .

Then  $K \simeq E^*(-2m-1)$ , and  $\exists \eta \in H^2(S^2 E^*(-2m-1))$  under the canonical decomposition

$$\text{Ext}^2(E, E^*(-2m-1)) \simeq H^2(S^2 E^*(-2m-1)) \oplus H^2(\wedge^2 E^*(-2m-1))$$

such that  $V$  presents  $\ker \Phi(\eta)$ .

Conversely, if  $\eta \in H^2(S^2 E^*(-2m-1))$ ,  $\mu = \Phi(\eta)$  satisfies

**Theorem B**, and  $\ker V \simeq E^*(-2m-1)$ ,  $V$  is skew-symmetrizable.

# One explicit example

## Theorem II, revisited.

When  $E$  is a 2-instanton bundle or a generic 4-instanton, the map  $\Phi : \text{Ext}^2(E, E^*(-2m-1)) \rightarrow \text{Hom}_R(\mathbf{E}, \mathbf{M})_0$  is a surjection, and the assumptions of **Theorem B** are satisfied.

Example. Let's construct a  $10 \times 10$  skew-symm matrix of linear forms in 4 variables with constant rank 8, starting from a 2-instanton on  $\mathbb{P}^3$ .

Remark. there used to be **only one example** of this type of spaces, in [Westwick '96].
